

Part 1

1. Brand Listing Write a query to list all **product names** along with their corresponding **brand names**. Sort the results alphabetically by brand name.

2. Store Contact List Retrieve a list of all **staff members**, including their first and last names, and the **store name** where they work.

3. Customer Order History Show all **orders** (order ID and order date) along with the **customer's full name** (first and last) who placed them. Order the results by the order date in descending order (most recent first).

Part 2

4. Category Stock Levels Calculate the **total quantity** of products in stock for each **category name**. Group the results by category and use a HAVING clause to only show categories that have more than 500 items in total stock.

5. Sales Performance by Store Find the **total sales amount** (calculated as quantity * list_price) generated by each **store**. Display the store name and the total sales revenue, ordered from the highest revenue to the lowest.

6. Product Pricing Tiers List all products, their category names, and their list prices. Use a CASE statement to create a new column called 'Price_Segment' that labels them as:

- **'Budget'** (if price is under \$500)
- **'Mid-Range'** (if price is between \$500 and \$2000)
- **'Premium'** (if price is over \$2000)

7. Bulk Order Summary For each order, find the total number of distinct products ordered. Display the **Order ID** and the **Product Count**, but only for orders that contain more than 3 different products.

Part 3

8. Brand Performance Analysis Identify the **brands** that have sold more than 100 units in total. Your output should include the **Brand Name**, the total **Quantity Sold**, and a CASE statement that flags the brand as "**Top Performer**" if sales exceed 500 units, and "**Standard**" otherwise. (Hint: Join brands, products, and order_items).

9. Staff Sales Activity Find all **staff members** who have handled more than 50 orders. Display their full name (concatenated), their store name, and the total count of orders they processed. Sort the output alphabetically by store name, and then by the order count in descending order.

10. Discount Impact Analysis Analyze the revenue lost to discounts across different product categories. For every **product category**, calculate:

- The total potential revenue (if there were no discounts).
- The actual revenue (applying the discount column).
- The total dollar amount of discounts given. Use GROUP BY and HAVING to only show categories where the total discount amount given exceeds \$5,000.
