

1. Customer Base by Region Tier Write a query using the customers table to group customers by their state. Use a CASE expression within the SELECT and GROUP BY clauses to label 'NY' as 'East Coast', 'CA' as 'West Coast', and any other state as 'Other Region'. Only display region groups that have a total customer count greater than 30.

2. Product Category Stock Evaluation Write a query using the products table to group items by their category ID. Use a CASE expression to count how many products in each category are 'Expensive' (price over \$2,000). Filter your final results using a HAVING clause to only show category IDs that have more than 5 expensive products.

3. Order Volume by Seasonal Quarters Write a query using the orders table to analyze order volumes based on when they were placed. Use a CASE expression to group the order_date values into 'First Half' (months January through June) and 'Second Half' (months July through December). Use a WHERE clause to only look at orders from the year 2018, and use a HAVING clause to only show halves that processed more than 200 orders.

4. High-Value Item Density in Orders Write a query using the order items table to find out which unique orders contain a heavy amount of premium items. Group the rows by order_id. Use a CASE expression to calculate the total quantity of items in that order where the list_price is greater than \$1,000. Display only the order IDs where the total quantity of these premium items is strictly greater than 3.

5. Store Order Status Performance Write a query using the orders table to find stores that have an elevated number of unfulfilled requests. Group the records by store_id. Filter the data first using a WHERE clause to only look at orders placed in 2018. Then, use a CASE expression inside a HAVING clause to only display store IDs that have more than 15 orders marked with a status other than 'Shipped' (where order_status is not equal to 4).
